

# VeCroToken: An Efficient, Verifiable, and Privacy-Preserving Cross-Chain Model for Consortium Blockchains Based on zk-SNARKs (Supplementary Material)

Ke Ding, Xiaoyan Hu, Weicheng Zhou, Guang Cheng, Ruidong Li, and Hua Wu

## S1. INTRODUCTION

This supplementary material provides a Universal Composability (UC) treatment that unifies transaction-security (verifiability, balance safety, no double-spending) and privacy (amount, balance, fund-correlation) using an ideal functionality  $\mathcal{F}_{\text{VCT}^*}$ . In  $\mathcal{F}_{\text{VCT}^*}$ , local prechecks return **FAIL** without any public footprint. Invalid outcomes are triggered by the result of a cross-chain verification service  $\mathcal{F}_{\text{XVer}}$ . Transfers follow a single-consumption relay state machine  $\text{Send} \rightarrow \{\text{Finished}, \text{Invalid}\}$ . We provide the UC proof with a simulator, a bridge lemma, a hybrid sequence, and explicit privacy bounds. Moreover, we provide detailed listings for construction.

## S2. SETTING AND NOTATION

We consider two consortium chains  $C, D$  and a relay chain  $R$  with deterministic finality (BFT). Each account  $a$  keeps a native balance  $v[a]$  and a zk-balance  $z[a]$ . The public conversion coefficient is  $n_c$ . Operations are **DEPOSIT**, **WITHDRAW**, **SEND**, **RECEIVE**. Each transfer has a unique identifier  $\text{Tid}$ .

## S3. GLOBAL FUNCTIONALITIES IN THE $(\mathcal{G}_{\text{Ledger}}, \mathcal{F}_{\text{CRS}}, \mathcal{F}_{\text{XVer}})$ -HYBRID WORLD

Fig. S1 summarizes  $\mathcal{G}_{\text{Ledger}}$  as the unique finalized log per chain, providing a deterministic total order and finality points. The later UC proof relies on this finality to serialize visible actions on the relay ledger  $L_R$  and to rule out post-finality rewrites.

### Global Ledger Functionality $\mathcal{G}_{\text{Ledger}}$ .

**State:** For each chain  $X \in \{C, D, R\}$ , a totally ordered log  $L_X$  with deterministic finality.

**Interfaces:**  $\text{Post}(X, \text{tx})$  appends to  $L_X$  and finalizes.  $\text{Read}(X, \text{qid})$  returns authenticated answers.

**Safety:** No two finalized entries share a  $\text{Tid}$ . Finalized order is consistent to all honest parties.

**Adversary:** May delay but cannot rewrite finalized entries nor create conflicting finalized states.

Fig. S1. Global ledger functionality  $\mathcal{G}_{\text{Ledger}}$ .

Fig. S2 depicts  $\mathcal{F}_{\text{CRS}}$ , which provisions the CRS and circuit keys. The zero-knowledge simulator trapdoor is available only to the ideal-world simulator  $S$ . No application plaintexts or balances are exposed by  $\mathcal{F}_{\text{CRS}}$ .

### CRS Functionality $\mathcal{F}_{\text{CRS}}$ .

On  $\text{Setup}(\lambda)$  sample a common reference string CRS and publish it to all parties and the adversary. For each circuit type  $i \in \{\text{dep}, \text{wd}, \text{send}, \text{rece}\}$ , parties register  $(\text{pk}_i, \text{vk}_i)$  consistent with CRS. A simulation trapdoor for zk-SNARKs is available to the simulator only.

Fig. S2. CRS functionality  $\mathcal{F}_{\text{CRS}}$ .

**Cross-Chain Verification Functionality  $\mathcal{F}_{XVer}$  (CrossVerify).**

**Goal:** Mediate all cross-chain checks. Its *Accept/Reject* result triggers whether  $\mathcal{F}_{VCT^*}$  will publicly output *Invalid*.

**State:** Consults  $\mathcal{G}_{Ledger}$  and uses the relay log  $L_R$  for visible actions.

**Interfaces:**

**VerifyDep(Tid):** Fetch  $Tx$  by Tid from source ledger. If  $Tx.sta \neq \text{Valid}$  return *Reject*. Parse  $\chi = \{\text{pubk}, E_z, E_z^*, E_v, E_v^*\}$  and proof  $\pi_{dep}$ . Compute  $r \leftarrow \Pi.\text{Verify}(\text{vk}_{dep}, \chi, \pi_{dep})$ . If  $r = 1$  then  $\text{Post\_R}(R_{AccN}, Tx)$  to  $L_R$  and return *Accept*, else *Reject*.

**VerifyWd(Tid):** Same with  $\chi = \{\text{pubk}, E_z, E_z^*, E_v, E_v^*\}$  and  $\pi_{wd}$ . On  $r = 1$   $\text{Post\_R}(R_{AccN}, Tx)$ .

**VerifySend(Tid<sub>A</sub>, M):** Parse  $\chi = \{\text{pubk}_A, E_{zA}, E_{zA}^*, M\}$  and  $\pi_{send}$ . Compute  $r \leftarrow \Pi.\text{Verify}(\text{vk}_{send}, \chi, \pi_{send})$ . If  $r = 1$  set  $Tx.sta = \text{Send}$  and  $\text{Post\_R}(Tx_{send})$  to  $L_R$ , else *Reject*.

**VerifyRece(Tid<sub>A</sub>, Tid<sub>B</sub>, M<sub>rece</sub>, E<sub>zB</sub>):** Parse  $\chi = \{\text{pubk}_B, E_{zB}, E_{zB}^*, M_{rece}\}$  and  $\pi_{rece}$ . Obtain  $Tx_{send}$  via Tid<sub>A</sub> from  $L_R$  and parse  $M_{send}$  and  $sta$ . Obtain  $E_{zB}^{ledger}$  from chain  $D$ 's account certificate. *Accept* iff  $\Pi.\text{Verify}(\text{vk}_{rece}, \chi, \pi_{rece}) = 1 \wedge M_{rece} = M_{send} \wedge E_{zB} = E_{zB}^{ledger} \wedge sta = \text{Send}$ . On reject: set  $sta_{send} = \text{Invalid}$  and  $\text{Post\_R}(Tx_{send})$ . Return *Reject*. On accept: set  $sta_{send} = \text{Finished}$ ,  $\text{Post\_R}(Tx_{send})$  and  $\text{Post\_R}(R_{AccN}, Tx_{rece})$ . Return *Accept*.

**Remarks:** All four interfaces perform a visible  $\text{Post\_R}$  on *Accept*. *RECEIVE* additionally annotates Tid<sub>A</sub> as *Finished/Invalid*.

Fig. S3. Cross-chain verification functionality  $\mathcal{F}_{XVer}$ .

### S3.1 Sufficiency of $\mathcal{F}_{XVer}$ Checks for Integrity

Fig. S3 summarizes the CrossVerify interfaces and their visible actions. The two explicit checks in **VerifyRece**, namely  $M_{rece} = M_{send}$  and  $E_{zB} = E_{zB}^{ledger}$  with  $sta = \text{Send}$ , can prevent identity forgery and amount tampering.

**Lemma 1** (Integrity via Pair-Consistency and Identity-Binding). *Suppose the zk-SNARK system is knowledge-sound and  $\mathcal{G}_{Ledger}$  provides deterministic finality. If  $\mathcal{F}_{XVer}$  accepts a *RECEIVE* with  $\Pi.\text{Verify}(\text{vk}_{rece}, \chi, \pi_{rece}) = 1$ ,  $M_{rece} = M_{send}$ ,  $E_{zB} = E_{zB}^{ledger}$  and the paired send has  $sta = \text{Send}$ , then (i) the credited receiver is the ledger owner of  $E_{zB}^{ledger}$  (no identity forgery), and (ii) the transferred amount  $m$  equals the one committed to in the paired *SEND* (no amount tampering).*

*Proof.* Knowledge soundness of the accepting proof yields witnesses  $(z_B, z_B^*, m, k)$  satisfying the ciphertext-binding relations of Sec. S9:  $M_{rece} = E(m, k)$ ,  $E_{zB} = \text{EA}(z_B, \text{pubk}_B)$ ,  $E_{zB}^* = \text{EA}(z_B^*, \text{pubk}_B)$ , and the balance relation  $z_B^* - z_B = m$ . Equality  $M_{rece} = M_{send}$  pins the same  $m$  (and length) as used in the paired send's circuit. Otherwise two different witnesses would be required, contradicting soundness because the public input includes  $M$ . Equality  $E_{zB} = E_{zB}^{ledger}$  ties  $\text{pubk}_B$  to the ledger-certified receiver account. Forging a different identity would require either (a) ledger tampering (ruled out by  $\mathcal{G}_{Ledger}$ ), or (b) a second accepting proof with different public key but the same  $E_{zB}^{ledger}$ , which violates the circuit's key-consistency. Finally,  $sta = \text{Send}$  plus the relay SU invariant forces a single post-finality transition of Tid<sub>A</sub> to  $\{\text{Finished}, \text{Invalid}\}$ , precluding double credit or later mutation.  $\square$

**Mismatch handling and state sync.** If any of the three conditions fails,  $\mathcal{F}_{XVer}$  (i) rejects the receive, (ii) marks the paired Tid<sub>A</sub>  $\rightarrow \text{Invalid}$  if it exists, and (iii) posts the visible annotation to  $L_R$ . Because  $E_{zB}^{ledger}$  is read from  $C/D$  at finality, the relay state remains consistent with on-chain certificates. Future attempts with the same Tid<sub>A</sub> are blocked by SU.

## S4. LEAKAGE POLICY AND PUBLIC VIEW

Fig. S4 specifies the public view  $\mathcal{L}_{pub}$ : it reveals only the operation type, identifier Tid, status  $sta$ , verification key and proof, plus headers  $(M, \text{optionally } E_k/E_z)$  and basic metadata/lengths. Plaintext amounts and balances are never leaked.

**Public Leakage  $\mathcal{L}_{pub}$ .**

The ideal world exposes only: operation type; Tid and  $sta$ ; verification keys; zk-SNARK proofs; headers  $(M, E_k, E_z)$ ; metadata such as heights, timestamps; and lengths. No plaintext amounts or balances leak. The optional  $E_z$  is present in *RECEIVE* to support identity-binding.

Fig. S4. Leakage visible to the environment.

**Functional form.** We formalize the leakage as a function

$$\mathcal{L}_{pub} : \text{Transcript} \longrightarrow \{\text{op}, \text{Tid}, \text{sta}, \text{vk}, \text{proof}, (M, E_k, E_z), \text{meta}, \text{len}\}$$

and define indistinguishability only over histories with identical  $\mathcal{L}_{pub}$  output (same preimage class).

### S5. $\mathcal{F}_{\text{VCT}^*}$ IDEAL FUNCTIONALITY WITH VISIBLE LEAKAGE

Fig. S5 instantiates  $\mathcal{F}_{\text{VCT}^*}$ . Local prechecks return FAIL without any public footprint. Visible outcomes are driven by  $\mathcal{F}_{\text{XVer}}$ . For RECEIVE, pair consistency  $M_{\text{rece}} = M_{\text{send}}$  and identity-binding  $E_{z_B} = E_{z_B}^{\text{ledger}}$  are checked by  $\mathcal{F}_{\text{XVer}}$  (outside the circuit). On RECEIVE/Accept, the relay annotates  $\text{Tid}_A \rightarrow \text{Finished}$ . On RECEIVE/Reject, it annotates  $\text{Tid}_A \rightarrow \text{Invalid}$ .

#### Ideal Functionality $\mathcal{F}_{\text{VCT}^*}$ .

##### Internal State:

- (i) Balances: for each account  $a$ ,  $(v[a], z[a])$ .
- (ii) Transaction index  $Tx[\text{Tid}] = \{\text{kind} \in \{\text{dep}, \text{wd}, \text{send}, \text{rece}\}, \text{sta}, \text{owner}, \text{peer}, m, M, E_k, \underline{E_z}\}$ , where only  $m$  is private.
- (iii) Status  $\text{sta} \in \{\text{Valid}, \text{Invalid}, \text{Send}, \text{Receive}, \text{Finished}, \text{Deposit}, \text{Withdraw}\}$  is monotone.
- (iv) **Single-use Invariant (SU)**: any sending  $\text{Tid}_A$  transitions from Send to  $\{\text{Finished}, \text{Invalid}\}$  at most once and no updates thereafter.

**Public Leakage:** only  $\mathcal{L}_{\text{pub}}$  (as above).

##### Interfaces:

**DEPOSIT**( $a, m$ ). Local precheck:  $m > 0$  and  $\exists(v^*, z^*) : z^* - z[a] = m, v[a] - v^* = n_c m, v^* \geq 0$ . If not, **return FAIL** (no  $\mathcal{L}_{\text{pub}}$ ). Else, allocate  $\text{Tid}$ , set  $Tx[\text{Tid}] = \{\text{kind} = \text{dep}, \text{sta} = \text{Valid}, \text{owner} = a, m\}$ . Output  $\mathcal{L}_{\text{pub}}(\text{op} = \text{dep}, \text{Tid}, \text{sta} = \text{Valid})$ . Invoke  $\mathcal{F}_{\text{XVer}}.\text{VerifyDep}(\text{Tid})$ : on Accept, update  $(v[a], z[a]) \leftarrow (v^*, z^*)$ , set  $\text{sta} \leftarrow \text{Deposit}$  and output  $\mathcal{L}_{\text{pub}}(\text{op} = \text{dep}, \text{sta} = \text{Deposit})$ . On Reject(reason), set  $\text{sta} \leftarrow \text{Invalid}$  and output.

**WITHDRAW**( $a, m$ ). Local precheck:  $m > 0$  and  $\exists(v^*, z^*) : z[a] - z^* = m, v^* - v[a] = n_c m, z^* \geq 0$ . If not, **return FAIL**. Else, allocate  $\text{Tid}$ , set  $\text{sta} = \text{Valid}$  and output. Invoke  $\mathcal{F}_{\text{XVer}}.\text{VerifyWd}(\text{Tid})$ : on Accept set  $\text{sta} = \text{Withdraw}$ , update  $(v[a], z[a]) \leftarrow (v^*, z^*)$ , output. On Reject(reason) set  $\text{sta} = \text{Invalid}$ , output.

**SEND**( $a \rightarrow b, m$ ). Local precheck:  $m > 0$  and  $\exists z^* = z[a] - m \geq 0$ . If not, **return FAIL**, else: (1) allocate sender id  $\text{Tid}_A$ ; (2) derive header  $M = E(m, k)$  and key encapsulation  $E_k = \text{EA}(\text{pubk}_b, k)$ ; (3) set  $Tx[\text{Tid}_A] = \{\text{kind} = \text{send}, \text{sta} = \text{Valid}, \text{owner} = a, \text{peer} = b, m, M, E_k\}$  and output  $\mathcal{L}_{\text{pub}}(\text{op} = \text{send}, \text{Tid}_A, \text{sta} = \text{Valid}, M, E_k)$ ; (4) invoke  $\mathcal{F}_{\text{XVer}}.\text{VerifySend}(\text{Tid}_A, M)$ : on Accept set  $\text{sta}(\text{Tid}_A) = \text{Send}$ , update  $z[a] \leftarrow z[a] - m$ , output  $\mathcal{L}_{\text{pub}}(\text{op} = \text{send}, \text{Tid}_A, \text{sta} = \text{Send})$ . On Reject(reason) set  $\text{sta} = \text{Invalid}$  and output.

**RECEIVE**( $\text{Tid}_A$ ). Local precheck: there exists a send with  $Tx[\text{Tid}_A].\text{sta} = \text{Send}$ . If not, **return FAIL**, else: (1) allocate receiver id  $\text{Tid}_B$ ; (2) set  $Tx[\text{Tid}_B] = \{\text{kind} = \text{rece}, \text{sta} = \text{Valid}, \text{owner} = \text{peer}(\text{Tid}_A), \text{peer} = \text{owner}(\text{Tid}_A), m, M, E_k\}$  and output  $\mathcal{L}_{\text{pub}}(\text{op} = \text{rece}, \text{Tid}_B, \text{sta} = \text{Valid}, M, E_k, E_z)$ ; (3) invoke  $\mathcal{F}_{\text{XVer}}.\text{VerifyRece}(\text{Tid}_A, \text{Tid}_B, M_{\text{rece}}=M, E_{z_B})$ : on Accept set  $z[\text{owner}(\text{Tid}_B)] \leftarrow z[\text{owner}(\text{Tid}_B)] + m$ , set  $Tx[\text{Tid}_B].\text{sta} = \text{Receive}$  and output. On Reject(reason) set  $Tx[\text{Tid}_B].\text{sta} = \text{Invalid}$  and mark  $\text{Tid}_A \rightarrow \text{Invalid}$ .

Fig. S5. Ideal functionality  $\mathcal{F}_{\text{VCT}^*}$

### S6. CONCURRENCY AND SERIALIZABILITY UNDER $\mathcal{G}_{\text{Ledger}}$

Concurrent executions of cross-chain transfers preserve safety and privacy without additional mechanisms. First,  $\mathcal{G}_{\text{Ledger}}$  exports a single totally ordered log per chain with deterministic finality. Hence, any two relay actions have a well-defined order in  $L_R$ . Second, RSM (Fig. S6) and the SU invariant operate per  $\text{Tid}_A$  and are idempotent: two RECEIVE annotations for the same  $\text{Tid}_A$  commute to the unique terminal label in  $\{\text{Finished}, \text{Invalid}\}$ . Third,  $\mathcal{F}_{\text{XVer}}$  reads only finalized certificates and relay entries. Thus, its decisions are functions of immutable inputs.

**Lemma 2** (Serializability). *Let  $h$  be any concurrent history produced by the real protocol (or  $\mathcal{F}_{\text{VCT}^*}$  with  $S$ ). Then there exists a permutation  $\pi$  that orders all visible relay steps by their ledger-finalized positions such that executing the steps sequentially in order  $\pi$  yields the same public transcript and the same  $\mathcal{F}_{\text{VCT}^*}$  state.*

*Proof.* Because  $L_R$  is totally ordered at finality, ordering by finality induces a legal sequential schedule. Per- $\text{Tid}_A$  single-use prevents write-write races on the same entry. Different  $\text{Tid}$  values touch disjoint state except for reads of finalized certificates. Thus, operations on different  $\text{Tid}$  commute.  $\square$

**Privacy under concurrency.** The hybrids are defined over the entire transcript, independent of interleaving. Replacing proofs and swapping ciphertexts commute with merging histories. Therefore, the privacy theorems remain valid for arbitrary concurrency.

### S7. RELAY STATE MACHINE: VISIBLE ACTIONS AND INVARIANT

Fig. S6 shows the relay state machine per sender identifier  $\text{Tid}_A$ : a single terminal transition  $\text{Send} \rightarrow \{\text{Finished}, \text{Invalid}\}$  enforces the single-use invariant SU. A RECEIVE/Accept triggers Finished, and a RECEIVE/Reject triggers Invalid.

Non-terminal retries are not permitted. Concurrent visible steps are ordered by finality on  $L_R$ , and relay writes are idempotent post-finality.

**Relay State Machine RSM (publicly visible).**

State per  $Tid_A$ :  $\perp \xrightarrow{\text{Send}} \text{Send} \xrightarrow{\text{Receive/Reject}} \{\text{Finished}, \text{Invalid}\}.$

**Visible actions:**

(1)  $\text{Post\_R}(Tid_A, \text{Send}, M)$ ; (2)  $\text{Annotate\_R}(Tid_A, \text{Finished})$ ; (3)  $\text{Annotate\_R}(Tid_A, \text{Invalid})$ ; (4)  $\text{Read\_R}(Tid_A)$ .

**SU:** For any  $Tid_A$ , at most one transition  $\text{Send} \rightarrow \{\text{Finished}, \text{Invalid}\}$ , and no updates afterwards.

**Enforcement:**  $\mathcal{G}_{\text{Ledger}}$  provides deterministic finality. RSM writes are idempotent and reject any second post-finality update for the same  $Tid_A$ .

*Note:* DEPOSIT, WITHDRAW, and RECEIVE also issue  $\text{Post\_R}$  events (Fig. S3) but they do not affect SU, which is defined per-sender  $Tid_A$ .

Fig. S6. Relay state machine and single-consumption invariant.

## S8. SECURITY MODEL AND ASSUMPTIONS

- **Adversary & Corruption.** The adversary  $\mathcal{A}$  is PPT and corruption is static. The environment  $\mathcal{Z}$  supplies inputs and observes outputs restricted to  $\mathcal{L}_{\text{pub}}$ .
- **Ledgers.**  $\mathcal{G}_{\text{Ledger}}$  offers deterministic finality and safety: the adversary may delay delivery but cannot rewrite finalized states nor create conflicting finalized histories.
- **CRS/ZK.**  $\mathcal{F}_{\text{CRS}}$  samples CRS. zk-SNARKs are complete, knowledge-sound, and zero-knowledge with a simulator trapdoor available to  $\mathcal{S}$  only.
- **CrossVerify.**  $\mathcal{F}_{\text{XVer}}$  mediates all cross-chain decisions. Invalid is triggered only by  $\mathcal{F}_{\text{XVer}}$ 's Reject, while  $\mathcal{F}_{\text{VCT}^*}$  emits the public  $L_{\text{pub}}$  reflecting the decision.  $\mathcal{F}_{\text{XVer}}$  may delay but not violate ledger safety or SU, which relies on  $\mathcal{G}_{\text{Ledger}}$ .
- **Primitives.** Signatures are EUF-CMA. Encryption EA is IND-CPA with unique decodability. Payload encryption E is IND-CPA. Commitments are binding and hiding.
- **Scope Declaration.** Joint attacks that combine zk-proof forgery with collusive ledger rewriting are out of scope:  $\mathcal{G}_{\text{Ledger}}$  already rules out any alteration of finality or fabrication of conflicting finalized states. Cross-chain node collusion can at most cause delays/withholding, not ledger tampering.

## S9. REAL PROTOCOL II: STATEMENT–WITNESS RELATIONS

Each operation has a zk-SNARK  $C_i$  with public inputs (headers/keys/status) and private witness  $(v, z, v^*, z^*, m, k)$ . The relations are composed of balance/amount constraints and ciphertext-binding constraints:

**Balance/amount constraints.**

$$\begin{aligned} \text{DEPOSIT: } z^* - z &= m, \quad v - v^* = n_c m, \quad v^* \geq 0, \\ \text{WITHDRAW: } z - z^* &= m, \quad v^* - v = n_c m, \quad z^* \geq 0, \\ \text{SEND: } z_A^* &= z_A - m, \quad m > 0, \quad z_A^* \geq 0, \\ \text{RECEIVE: } z_B^* - z_B &= m. \end{aligned}$$

**Ciphertext-binding constraints.**

$$\begin{aligned} \text{DEPOSIT: } E_z &= \text{EA}(z, \text{pubk}), \quad E_{z^*} = \text{EA}(z^*, \text{pubk}), \quad E_v = \text{EA}(v, \text{pubk}), \quad E_{v^*} = \text{EA}(v^*, \text{pubk}); \\ \text{WITHDRAW: } E_z &= \text{EA}(z, \text{pubk}), \quad E_{z^*} = \text{EA}(z^*, \text{pubk}), \quad E_v = \text{EA}(v, \text{pubk}), \quad E_{v^*} = \text{EA}(v^*, \text{pubk}); \\ \text{SEND: } M &= \text{E}(m, k), \quad E_{z_A} = \text{EA}(z_A, \text{pubk}_A), \quad E_{z_A^*} = \text{EA}(z_A^*, \text{pubk}_A); \\ \text{RECEIVE: } M_{\text{rece}} &= \text{E}(m, k), \quad E_{z_B} = \text{EA}(z_B, \text{pubk}_B), \quad E_{z_B^*} = \text{EA}(z_B^*, \text{pubk}_B). \end{aligned}$$

In particular, the pair-consistency  $M_{\text{rece}} = M_{\text{send}}$  and the identity-binding predicate  $E_{z_B} = E_{z_B}^{\text{ledger}}$  are **not** part of the zk-circuit. They are checked by  $\mathcal{F}_{\text{XVer}}$  during RECEIVE.

### S9.1 Adversarial Scheduling and Conflict Handling in $\mathcal{S}$

**State kept by  $\mathcal{S}$ .** (i) A map  $T[\text{Tid}]$  to the latest visible relay status; (ii) a de-dup set  $Q$  of processed query identifiers; (iii) a buffer  $B$  of pending adversarial posts with delivery times.

**Delay & reordering.**  $\mathcal{S}$  forwards adversarial posts to  $\mathcal{G}_{\text{Ledger}}$  through the external scheduling interface and may delay/reorder them arbitrarily before finality, but it must not change the order of finalized items returned by  $\mathcal{G}_{\text{Ledger}}$ . Reads are answered by polling  $L_X$  until the requested entry reaches finality (or timeouts dictated by  $\mathcal{Z}$ ), then emitting only  $\mathcal{L}_{\text{pub}}$ .

**Replay/duplication.** On any adversarial replay with the same  $Tid$  or query identifier,  $\mathcal{S}$  responds with the already visible outcome, ensuring idempotence. For **RECEIVE**, a second annotation for the same  $Tid_A$  is rejected and  $T[Tid_A]$  remains unchanged by  $SU$ .

**Conflicting transactions.** If the adversary submits conflicting **SEND** transactions with the same  $Tid_A$ ,  $\mathcal{S}$  relays both to  $\mathcal{G}_{Ledger}$ , but only the unique finalized one is used by  $\mathcal{F}_{XVer}$ . If two conflicts were finalized (ruled out by  $\mathcal{G}_{Ledger}$ 's safety), the reduction in Sec. S12 would extract a violating accepting proof. For **RECEIVE**, if  $(M_{rece}, E_{zB})$  conflicts with the paired send or with the ledger certificate,  $\mathcal{S}$  invokes  $\mathcal{F}_{XVer}$  which rejects and marks  $Tid_A \rightarrow \text{Invalid}$ .

$\mathcal{G}_{Ledger}$ - $\mathcal{F}_{VCT^*}$  **synchronization.**  $\mathcal{S}$  mirrors every finalized relay action into  $\mathcal{F}_{VCT^*}$ 's internal  $Tx[\cdot]$  and status map before emitting the corresponding  $\mathcal{L}_{pub}$  item. Thus, the visible transcript and the ideal state remain consistent. Any subsequent environment query is answered from  $T$  and the finalized  $L_R$ .

We encode the balance updates and ciphertext-binding relations in a standard RICS form. Any IND-CPA PKE and symmetric encryption scheme can be used as long as the public inputs expose key-consistency.

#### S10. DETAILED SIMULATOR $\mathcal{S}$ IN THE IDEAL WORLD

Fig. S7 outlines the ideal-world simulator  $\mathcal{S}$ . It emits only  $\mathcal{L}_{pub}$ , delegates cross-chain decisions to  $\mathcal{F}_{XVer}$ , and mirrors finalized relay annotations. On **RECEIVE/Reject**,  $\mathcal{S}$  records  $Tx_{rece} = \text{Invalid}$  and annotates the paired  $Tid_A \rightarrow \text{Invalid}$ . On **RECEIVE/Accept**, it annotates  $Tid_A \rightarrow \text{Finished}$  and outputs the updated relay/account records.

##### Simulator $\mathcal{S}$ .

**World:**  $(\mathcal{G}_{Ledger}, \mathcal{F}_{CRS}, \mathcal{F}_{XVer}, \mathcal{F}_{VCT^*})$ -hybrid.  $\mathcal{S}$  controls the adversarial interface and produces only  $\mathcal{L}_{pub}$ .

On **DEPOSIT/WITHDRAW** from a corrupt party: perform the same local precheck as  $\mathcal{F}_{VCT^*}$ . On failure, return **FAIL** (no output). On success, register **Valid** in  $\mathcal{F}_{VCT^*}$ . Simulate an accepting zk-proof via  $\mathcal{F}_{CRS}$  and emit  $\mathcal{L}_{pub}(\text{sta} = \text{Valid})$ . Then call  $\mathcal{F}_{XVer}.\text{VerifyDep/Wd}$  and emit the resulting terminal state (**Deposit/Withdraw** or **Invalid**).

On **SEND**: precheck or **FAIL**. Otherwise register  $Tid_A$  with  $\text{sta} = \text{Valid}$ , emit  $\mathcal{L}_{pub}$  with simulated proof. Call  $\mathcal{F}_{XVer}.\text{VerifySend}$ . On **Accept**, set  $\text{sta} = \text{Send}$ , decrease  $z[a]$ , emit. On **Reject**, set **Invalid**.

On **RECEIVE**( $Tid_A, E_{zB}$ ): require  $Tx[Tid_A].\text{sta} = \text{Send}$ . Else **FAIL**. Register  $Tid_B$  with  $\text{sta} = \text{Valid}$ , include  $E_{zB}$  in  $L_{pub}$ , emit. Call  $\mathcal{F}_{XVer}.\text{VerifyRece}$ . On **Accept**, credit receiver, set  $\text{sta}(Tid_B) = \text{Receive}$  and rely on  $\mathcal{F}_{XVer}$  to annotate  $Tid_A \rightarrow \text{Finished}$ . On **Reject**, set  $\text{sta}(Tid_B) = \text{Invalid}$  and annotate  $Tid_A \rightarrow \text{Invalid}$ .

**SU:**  $\mathcal{S}$  rejects any second annotation after finality, keeping  $\text{Send} \rightarrow \{\text{Finished}, \text{Invalid}\}$  single-consumption.

Fig. S7. Simulator behavior and visible actions.

#### S11. HYBRID SEQUENCE FOR THE MAIN UC THEOREM

We use a four-step sequence. Let  $\mathcal{Z}$  be any PPT environment and  $\mathcal{A}$  any PPT real-world adversary.

**H<sub>0</sub> (Real).** Real execution of  $\Pi$  with  $\mathcal{A}$  in the  $(\mathcal{G}_{Ledger}, \mathcal{F}_{CRS}, \mathcal{F}_{XVer})$ -hybrid model.

**H<sub>1</sub> (Witness-Stripping via ZK).** Replace every accepting zk-SNARK proof in  $H_0$  by a simulated proof for the same public statement using the trapdoor from  $\mathcal{F}_{CRS}$ . Witnesses are never used.

**Lemma 3** ( $H_0 \stackrel{c}{\approx} H_1$ ). *By zk-SNARK zero-knowledge,  $\mathcal{Z}$  cannot distinguish  $H_0$  from  $H_1$  except with negl advantage.*

**H<sub>2</sub> (Cipher/Commit Swap).** Independently and operation-wise, replace each amount/auxiliary ciphertext (and balance commitments if any) by encryptions/commitments of length-matching dummies.

**Lemma 4** ( $H_1 \stackrel{c}{\approx} H_2$ ). *By IND-CPA and commitment hiding,  $\mathcal{Z}$  cannot distinguish  $H_1$  from  $H_2$  except with negl advantage.*

**H<sub>3</sub> (Ideal + Simulator).** Replace the real protocol by the simulator  $\mathcal{S}$  of Fig. S7 interacting with  $\mathcal{F}_{VCT^*}$  and  $\mathcal{F}_{XVer}$  and emulating the relay via its visible actions.  $\mathcal{S}$  outputs exactly  $\mathcal{L}_{pub}$  and enforces **SU** via **RSM**.

**Lemma 5** ( $H_2 \stackrel{c}{\approx} H_3$ ). *The public distribution in  $H_2$  equals that in  $H_3$ : both expose only  $\mathcal{L}_{pub}$  and identical status transitions. Any deviation would either violate **SU**, contradicting Fig. S6 with  $\mathcal{G}_{Ledger}$  finality, or create an accepting proof without a valid statement, contradicting soundness.*

**Lemma 6** (Bridge Lemma: Ledger  $\rightarrow$  Atomicity). *If  $\mathcal{G}_{Ledger}$  provides deterministic finality and the relay state machine enforces **SU**, then for any  $Tid_A$  the public transcript admits no observable intermediate state between **Send** and  $\{\text{Finished}, \text{Invalid}\}$ . Hence, the transition is atomic and  $Tid_A$  cannot be consumed twice.*

**Theorem 1** (Main UC Theorem: Verifiability & Balance Safety). *For every PPT  $\mathcal{A}$  there exists a PPT  $\mathcal{S}$  such that  $\text{EXEC}_{\Pi, \mathcal{A}, \mathcal{Z}}^{\text{real}} \stackrel{c}{\approx} \text{EXEC}_{\mathcal{F}_{VCT^*}, \mathcal{F}_{XVer}, \mathcal{S}, \mathcal{Z}}^{\text{ideal}}$  in the  $(\mathcal{G}_{Ledger}, \mathcal{F}_{CRS}, \mathcal{F}_{XVer})$ -hybrid model.*

*Proof.* Chain the lemmas:  $H_0 \stackrel{c}{\approx} H_1 \stackrel{c}{\approx} H_2 \stackrel{c}{\approx} H_3$ .  $H_3$  is the ideal execution with  $\mathcal{S}$  talking to  $\mathcal{F}_{\text{VCT}^*}$  and  $\mathcal{F}_{\text{XVer}}$ . Verifiability follows from soundness (no false acceptance), and balance safety from per-operation relations and SU (no double-consumption), strengthened by the Bridge Lemma.  $\square$

## S12. REDUCTION CONSTRUCTION AND PROBABILITY QUANTIFICATION

We formalize the stepwise reduction that captures overspend/false-accept as a break of zk-SNARK soundness.

**Lemma 7** (Soundness-Reduction Lemma). *Let  $\mathcal{A}$  be any PPT adversary that, in the real world, causes an accepting transaction that violates the corresponding relation (overspend, balance underflow, or acceptance of a mismatched Send/Receive pair). Consider a single-circuit SNARK soundness game for  $C_j \in \{\text{dep}, \text{wd}, \text{send}, \text{rece}\}$ , and let the reduction  $\mathcal{R}$  guess  $j$  uniformly at random. Then*

$$\Pr[\mathcal{R} \text{ breaks SNARK}] \geq \frac{1}{4} \Pr[E_{\text{over}} \vee E_{\text{false}}] - \text{negl}(\lambda). \quad (1)$$

*Proof.*  $\mathcal{R}$  joins the soundness game for a randomly chosen circuit  $C_j$  under CRS set by the challenger. It sets the system CRS to this value and runs  $\mathcal{A}$  unchanged. It emulates ledgers via  $\mathcal{G}_{\text{Ledger}}$  and keeps shadow balances from  $\mathcal{L}_{\text{pub}}$ . Whenever  $\mathcal{A}$  outputs a finalized accepting transaction  $(x, \pi)$  of type  $C_j$ :

- If it triggers  $E_{\text{over}}$ , i.e., a relation violation occurs, output  $(x, \pi)$ .
- If it triggers  $E_{\text{false}}$ , i.e., the Send/Receive pair is inconsistent, output  $(x, \pi)$ .

If the violating transaction is for circuit  $C_i$ ,  $\mathcal{R}$  succeeds exactly when  $j = i$ , which occurs with probability  $1/4$ . Conditioning on the bad event and averaging over the guess yields the factor  $1/4$  in (1). Repeated consumption either violates SU (absorbed in  $\text{negl}$ ) or implies an inconsistent accepting proof covered above.  $\square$

## S13. PRIVACY THEOREMS

We write  $\text{View}^{H_i}$  for the environment's view in  $H_i$ , and all indistinguishability arguments below are taken with respect to the same hybrid sequence.

### S13.1 Quantitative Advantage Accounting

Let  $\Delta_i := |\Pr[\text{View}^{H_i} \in \mathcal{W}] - \Pr[\text{View}^{H_{i+1}} \in \mathcal{W}]|$  for any distinguisher/event  $\mathcal{W}$ . By the triangle inequality,

$$|\Pr[\text{View}^{H_0} \in \mathcal{W}] - \Pr[\text{View}^{H_3} \in \mathcal{W}]| \leq \sum_{i=0}^2 \Delta_i.$$

We now bound each  $\Delta_i$  by a standard reduction:

$$\begin{aligned} \Delta_0 &\leq \text{Adv}_{\Pi}^{\text{ZK}}(\lambda) && \text{(witness-stripping via the ZK simulator),} \\ \Delta_1 &\leq \text{Adv}_{\text{E}}^{\text{IND-CPA}}(\lambda) && \text{(cipher/commit swap for amounts and auxiliaries),} \\ \Delta_2 &\leq \text{negl}(\lambda) && \text{(syntactic replacement with the simulator that outputs only } \mathcal{L}_{\text{pub}} \text{).} \end{aligned}$$

Therefore the privacy advantage of any PPT distinguisher  $\mathcal{D}$  is at most

$$\text{Adv}_{\Pi}^{\text{priv}}(\lambda) \leq \text{Adv}_{\Pi}^{\text{ZK}}(\lambda) + \text{Adv}_{\text{E}}^{\text{IND-CPA}}(\lambda) + \text{negl}(\lambda).$$

For balance privacy replace the swapped components accordingly, namely balances and certificates, yielding the same bound.

### S13.2 Amount Privacy

**Definition 1** (Amount Privacy). *Let  $\text{View}^{\text{ideal\_amt}}$  be the distribution that replaces all plaintext amounts by dummies while preserving  $\mathcal{L}_{\text{pub}}$ .  $\Pi$  has amount privacy if  $\text{View}^{\text{real}} \stackrel{c}{\approx} \text{View}^{\text{ideal\_amt}}$ .*

**Theorem 2** (Amount Privacy).  *$\text{View}^{H_0} \stackrel{c}{\approx} \text{View}^{H_1}$  by ZK (witness-stripping), and  $\text{View}^{H_1} \stackrel{c}{\approx} \text{View}^{H_2}$  by IND-CPA. Hence,  $\text{View}^{H_0} \stackrel{c}{\approx} \text{View}^{H_2}$ . Since  $H_3$  only emits  $\mathcal{L}_{\text{pub}}$ ,  $\text{View}^{H_2} \stackrel{c}{\approx} \text{View}^{H_3}$ . Moreover,*

$$\text{Adv}_{\Pi}^{\text{amt-priv}} \leq \text{Adv}^{\text{ZK}} + \text{Adv}^{\text{IND-CPA}} + \text{negl}(\lambda).$$

### S13.3 Balance Privacy

**Definition 2** (Balance Privacy). *Define  $\text{View}^{\text{ideal\_bal}}$  by replacing pre/post balances or their commitments with dummies while preserving  $\mathcal{L}_{\text{pub}}$ .  $\Pi$  has balance privacy if  $\text{View}^{\text{real}} \stackrel{c}{\approx} \text{View}^{\text{ideal\_bal}}$ .*

**Theorem 3** (Balance Privacy). *ZK removes witness dependence ( $H_0 \rightarrow H_1$ ), and hiding (or IND-CPA if encrypted) swaps balances/commitments ( $H_1 \rightarrow H_2$ ), while  $H_2 \rightarrow H_3$  leaves only  $\mathcal{L}_{\text{pub}}$ . Moreover,*

$$\text{Adv}_{\Pi}^{\text{bal-priv}} \leq \text{Adv}^{\text{ZK}} + (\text{Adv}^{\text{Hiding}} \text{ or } \text{Adv}^{\text{IND-CPA}}) + \text{negl}(\lambda).$$

### S13.4 Fund-Correlation Privacy

**Definition 3** (Fund-Correlation Privacy). For two histories  $Q_0, Q_1$  that agree on  $\mathcal{L}_{\text{pub}}$  and on the multiset of hidden amounts and balance deltas but differ in pairings across users/time, the joint views are computationally indistinguishable.

**Theorem 4** (Fund-Correlation Privacy). In  $H_1$  witnesses are removed. In  $H_2$  ciphertexts/commitments are replaced by dummies that preserve only lengths. Pair-consistency  $M_{\text{rece}} = M_{\text{send}}$  is enforced by  $\mathcal{F}_{\text{XVer}}$  from the public transcript, thus  $\text{View}^{H_2}$  and  $\text{View}^{H_3}$  remain identical for any re-pairing preserving  $\mathcal{L}_{\text{pub}}$ . Therefore  $\text{View}^{H_0}$  is indistinguishable. Moreover,

$$\text{Adv}_{\Pi}^{\text{fund-corr}} \leq \text{Adv}^{\text{ZK}} + \text{Adv}^{\text{IND-CPA}} + \text{negl}(\lambda).$$

## S14. DETAILED LISTINGS FOR CONSTRUCTION

---

```

1 Paralnit
2   Compute  $\xi = \Pi.\text{Setup}(\lambda)$ 
3   Use  $\xi$  as the basic parameter
4   FOR each  $i \in \{\text{dep}, \text{wd}, \text{send}, \text{rece}\}$  DO
5     Compute  $(pk_i, vk_i) = \Pi.\text{GenKey}(C_i)$ 
6   END FOR
7   Output  $(pk_i, vk_i), i \in \{\text{dep}, \text{wd}, \text{send}, \text{rece}\}$
